### (54) Device for the control of electro-hydraulically actuated fuel injectors.

(57) The opening and closing movements of an injector valve member which closes and temporarily opens discharge orifices communicating with the combustion chamber of an internal combustion engine is controlled by the fuel pressure in a control chamber (350) arranged at one end of the injector valve member piston (336). Fuel is evacuated from said control chamber (350) through bores (348, 352, 366, 364) when a valve item (76) is lifted off its seat (70) to allow the opening of the injector valve member. Reseating the valve stem (76) results in temporarily moving an intermediate valve body (332) away from a seating surface (354) to provide fast refilling of the control chamber (350) with fuel flowing through bores (360) connected to an inlet bore (358). A sharp closure of the valve member is achieved.

EP 0 426 205 A2

## DEVICE FOR THE CONTROL OF ELECTRO-HYDRAULICALLY ACTUATED FUEL INJECTORS

### Technical Field

The present invention relates generally to a device for the control of the opening and closing movements of the injector needle valve of electro-hydraulically actuated fuel injectors as defined in the pre-characterising clause of claim 1.

### Background and Summary of the Invention

Different designs of electro-hydraulically actuated fuel injectors are disclosed in the US-A-3,610,529 and in the US-A-4,566,416. In these disclosed injectors the opening and closing movements of the injector needle valve member are controlled by the fuel pressure acting on both sides of an injector needle valve piston. The end surface of the needle valve piston opposite to the tip and seat of the injector needle valve is biased by the fuel pressure in a control chamber. An inlet orifice to this control chamber connects the latter to a high pressure fuel supply line. An outlet orifice from this control chamber can be opened and closed by an electromagnetically operated on-off pilot valve. Upon energization of a solenoid, the pilot valve retracts from its seat at the outlet orifice, opens the latter and, due to the restriction of the inlet orifice, the pressure in the control chamber drops sufficiently to allow for the opening motion of the injector needle valve member and the begin of the injection event. Reseating of the pilot valve after the end of the electric pulse to the solenoid results in a pressure rise in the control chamber due to the fuel entering the chamber through the inlet orifice. Upon this pressure rise the injector needle valve member will be closed and the injection event will be terminated.

In order to improve the combustion process of the related internal combustion engine a fast and clean end of the injection event is needed, which is provided by a fast closing event of the injector needle valve member. For a given engine size, a given size of injection orifices is needed, which determines the diameter of the needle valve seat and in turn the diameter of the needle valve piston. The larger the size of said inlet orifice, the faster the refilling of the control chamber and therefore the faster will be the closing movement of the injector needle valve member.

However, a large size of the inlet orifice also means a large size of the outlet orifice, since otherwise the pressure drop in the control chamber will not be sufficient. Since both orifices are fully open when the pilot valve is retracted, a consider-

able amount of fuel will bypass both orifices during the injection event. For typical injectors of this type, at full engine torque, in addition to the injected fuel 50% are bypassed through the two control orifices. At partial engine load this percentage increases and sometimes becomes larger than the injected fuel.

It is now the main object of the present invention to propose a device for the hydraulic control of the injector needle valve movement for injectors of the afore-mentioned type which allows a precise and always repeatable control of the opening and fast closing movement of the injector valve member with a greatly diminished need of fuel to implement said movements.

According to the present invention, this object is achieved by the features of the characterising part of claim 1.

In the FR 2 541 379-A1 and FR 2 543 647-A1 an injector with an electro-hydraulically operated needle valve member and a three-way valve to control the opening and closing movements of the needle valve member are proposed. The injector needle valve opening motion is slow due to the interposition of a sealing valve plate with an orifice between the end-surface of the needle valve piston and the discharge passage. The closing motion of the injector valve is fast, since the valve plate opens a larger section for the passage of fuel during the injector valve closing event. The fuel for the closing event is supplied through an inlet passage opened by means of the three-way valve. As a result, the design of the three-way valve is complicated and expensive to manufacture, particularly if the injector is supposed to operate at high fuel pressures.

In the present invention a simple on-off valve can be used to control the opening movement of the injector valve member, while during the initial phase of its closing movement an intermediate valve body will temporarily and automatically open fuel inlet passages of big size machined in a pressure control element for the fast closure of the injector needle valve member. These fuel inlet passages are substantially closed by the intermediate valve body during the opening movement of the injector valve member, thus minimizing the spillage of fuel across the pilot valve seat during the injection event.

An advantageous embodiment of the invention is discussed in the description below and shown in Figure 1, which is an enlarged fragmentary axial sectional view of the peculiar portion of an electro-hydraulically actuated fuel injector according to the present invention.

### Detailed Description of Figure 1

Figure 1 discloses the design of only the portion of an injector with electro-hydraulically actuated injector needle valve, according to the present invention, which controls the pressure in the control chamber on top of the injector needle valve piston. Reference is made to Figure 1 and also to Figures 4 and 5 of EP-A-0228578 regarding the design of the entire injector.

The needle valve piston 336 of the injector needle valve (which is only partially shown and which closes and temporarily opens fuel discharge orifices) shows an upper section 338 having a smaller diameter. On this smaller section 338 a spring 340 is placed. The opposite side of spring 340 is engaging a section of an intermediate valve body 332 having a reduced diameter, and this end of spring 340 is resting on a shoulder of the valve body 332. Between the upper part of the intermediate valve body 332 and the upper elongated section of a guide bore 342 for the needle valve piston 336, which is machined into an injector housing 344, an annular ring-shaped space 346 of a relatively big cross sectional area is provided. The intermediate valve body 332 is provided with a small bore 348, one end of which is connected with the control chamber 350 on top of the injector needle valve piston 336. The other end of the small bore 348 is connected to a bore 352 having a greater diameter machined in the intermediate valve body 332.

The intermediate valve body 332 has a seating surface 354 which acts together with the seating surface of a pressure control element 334. The control element 334 is provided with a ring bore 356 which is connected to the high pressure inlet connection (not shown) of the injector by a bore 358 of big cross sectional area. A number of bores 360 machined into the control element 334 connects the ring bore 356 with the seating surface of the control element 334. The seating surface 354 can be either flat as shown, or slightly spherical or also conical.

A small bore 362 connects the ring bore 356 with a small bore 364 machined on the longitudinal axis of the pressure control element 334. One end of the small bore 364 is connected to a seating surface 70 and can be opened and closed by the stem 76 of an electromagnetically operated on-off solenoid needle valve 72 (not shown in detail). The construction and operation of the solenoid needle valve 72 is shown and described in EP-A-0228578. The other end of the small bore 364 is connected to a bore 366 of greater diameter, which in turn is connected to the bore 352 machined into the intermediate valve body 332. The control element 334 and the injector needle valve piston 336 are tightly

fitted into guide bore 342 in order to minimize leakage of fuel from high to lower fuel pressure regions. Several alternative embodiments of the design of Figure 1 can be used, of which two shall be shortly discussed hereinafter. In a first alternative embodiment, for some applications it is more practical to make the guide bore 342 with two sections having different diameters, one guiding the needle valve piston 336, the other guiding the control element 334, which can also be press-fitted in the guide bore. Furthermore, instead of guiding the spring 340 on its inner diameter, the latter could be placed in a cylindrical recess of the needle valve piston 336, the recess guiding the spring 340 on its outer diameter. This solution minimizes the length of the guide bore 342.

The mode of operation of the embodiment of Figure 1 to allow for the pressure in the control chamber 350 to control the injector needle valve opening and closing motions is the following: prior to the beginning of the injection event, the intermediate valve body 332 is contacting the control element 334, thus the seating surface 354 substantially prevents the passage of fuel through the bores 360. When the solenoid needle valve 72 is retracted from its seat 70, the fuel pressure in the small bore 364 and consequently also in the larger bores 366 and 352, in the small bore 348 and finally in the control chamber 350 quickly drops, which causes the injector needle valve to be moved upwardly and to initiate the injection event as described in more detail in EP-A-0228578.

To terminate the injection event the solenoid needle valve 72 will first close the outlet of the small bore 364. Fuel will now flow from the small bore 362 through a part of the small bore 364 and increase the pressure in the larger bores 366 and 352. This, together with the fuel pressure prevailing in the bores 360 will momentarily move the intermediate valve body 332 off its engaged position with the control element 334. This results in a big flow area provided through the bores 360 and the ring-shaped space 346 to supply fuel in order to sharply close the injector needle valve.

A first advantage of this solution is therefore the provision of a very quick closing motion of the injector needle valve, while maintaining the control upon its opening motion. In addition, spillage of fuel through the small bore 364 during the injection event is greatly diminished compared to prior solutions.

In an alternate embodiment, the small bore 362 connects to the bore 366 instead of the small bore 364, which is more simple to machine.

In a second alternate embodiment, the small bore 348 in the intermediate valve body 332 is omitted, the bore 352 therefore connecting the control chamber 350 with the bore 366. In this case

the ring shaped space 346 is also omitted and the intermediate valve body 332 is guided with a relatively tight sliding fit in the guide bore 342. Appropriate sizing of the bore 352 will provide a large passage for the fuel from the bores 360 to the control chamber 350 during the closing movement of the injector valve member. The opening movement of the injector valve member is now controlled by the sections of the small outlet bore 364 and of the small bore 362. The momentary movement of the intermediate valve body 332 during the closing event of the injector valve member is triggered by the fuel pressure prevailing in the bores 360.

In a third alternate embodiment the small bore 362 is omitted. An adequate machining of a portion of the seating surface 354, for example with small radial grooves or with another method, provides the fuel pressure to trigger the momentary movement of the intermediate valve body 332 during the closing event of the injector valve member.

Combining one or more of the above discussed alternatives with the main features of the present invention allows the fine tuning of the opening and closing movements of the injector valve member to an optimum value for a given engine application.

The components determining the opening and closing movements of the injector valve member, which are: the stem 76 of the solenoid needle valve 72, the control element 334, the intermediate valve body 332 and the spring 340, can be placed in any appropriate location of the injector, aside from the control chamber 350, and therefore must not necessarily be placed as shown in Figure 1. These components can be placed at any angle compared to the longitudinal axis of the needle valve piston 336. In this case a connecting passage must connect the control chamber 350 with the side of the intermediate valve body 332 opposite to the seating surface 354.

As explained, the present invention allows a substantial reduction of the fuel spilled from the small bore 364 during the injection event. Due to this fact the small bore 364, for a given engine size, can be smaller compared to the prior art solutions. Therefore the reduced hydraulic force transmitted from the fuel pressure in the small bore 364 to the solenoid valve stem 76 allows the use of an electromagnetic actuator with reduced dimensions, which is a further advantage. However, a solenoid valve seat 70 sealing the small bore 364 right at its circumference must be used to exploit the above mentioned advantage. This is the case in the construction of Figure 1 with a flat seat 70. A slightly conical or spherical seat or generally a durable seat, sealing the bore 364 right at its circumference can also be used.

## Claims

1. Device for the control of the opening and fast closing movements of the injector valve member of an injector for intermittently injecting fuel into the combustion chamber of an internal combustion engine, comprising a housing (344), a piston member (336) urging the injector valve member in the closed position against a valve member seat provided with fuel discharge openings, a guiding bore (342) for said piston member (336) and a control chamber (350), said piston member (336) being subjected to the fuel pressure in said control chamber (350), said device further comprising an electromagnetically operable solenoid valve (72) having a stem (76), said stem (76) being in engagement with a solenoid valve seat (70) and being shiftable between an open and a closed position to open and close the outlet side of a discharge passage (364); characterised by at least one first passage (360) connected at one end to a seating surface (354) and at the other end to a fuel inlet passage (356, 358) of the injector of big cross sectional area, a valve body (332) engaging with said seating surface (354) at least during the opening movement of the injector valve member and therefore of the piston member (336) to substantially prevent fuel flow from said at least one first passage (360) into said control chamber (350), at least one second passage (352) in said valve body (332) connecting said control chamber (350) to said discharge passage (364), the opening movement of said stem (76) resulting in a pressure drop at least in said discharge passage (364), said second passage (352) and said control chamber (350) to allow for the opening movement of said piston member (336) and consequently of said injector valve member, the closing movement of said stem (76) and engagement with said seat (70) resulting in a momentary movement of said valve body (332) away from said seating surface (354), allowing fuel to flow from said at least one first passage (360) to said control chamber (350) to provide a fast closing movement of said piston member (336) of said injector valve member.
2. Device according to claim 1; wherein said at least one first passage (360) and said discharge passage (364) are placed in a cylindrical member (334) substantially and sealingly fitted in a bore (342) of said housing (344), said member (334) defining at one end side said seating surface (354) and at the other end side said solenoid valve seat (70).

3. Device according to claim 2; wherein an annular passage (356) machined either in said cylindrical member (334) or in said housing (344) connects said at least one first passage (360) to said fuel inlet passage (358). 5
4. Device according to claim 2; wherein said cylindrical member (334), said valve body (332) and said piston member (336) of said injector valve member are axially aligned. 10
5. Device according to the claims 1 or 2; wherein an additional throttling passage (362) connects said fuel inlet passage (358) with said discharge passage (364) or with another passage (366) connected at one end with said discharge passage (364) and at the other end with said at least one second passage (352) of said valve body (332). 15  
20
6. Device according to claim 1, wherein said valve body (332) comprises a throttling orifice (348) connected at one end with said control chamber (350) and at the other end with said second passage (352) and wherein said valve body (332) shows at least one connecting passage (346) between said seating surface (354) and said control chamber (350), the cross sectional area of said connecting passage (346) being substantially bigger than the cross sectional area of said throttling orifice (348). 25  
30
7. Device according to claim 1, wherein said valve body (332) is guided at its outer circumference in a bore (342) and fuel flow from the at least one first passage (360) to the control chamber (350) during the fast closing movement of said piston member (336) of said injector valve member takes place substantially through said passage (352) of said valve body (332). 35  
40
8. Device according to claim 1, wherein said seating surface (354) is essentially flat, slightly spherical or conical. 45
9. Device according to claim 1, wherein said stem (76), in its closed position engaging said solenoid valve seat (70), is closing off said discharge passage (364) essentially at its circumferential diameter at its outlet side. 50
10. Device according to claim 9, wherein said solenoid valve seat (70) and the tip of said stem (76) are constructed to form a flat seat. 55

### (54) Device for the control of electro-hydraulically actuated fuel injectors.

(57) The opening and closing movements of an injector valve member which closes and temporarily opens discharge orifices communicating with the combustion chamber of an internal combustion engine is controlled by the fuel pressure in a control chamber (350) arranged at one end of the injector valve member piston (336). Fuel is evacuated from said control chamber (350) through bores (348, 352, 366, 364) when a valve stem (76) is lifted off its seat (70) to allow the opening of the injector valve member. Reseating the valve stem (76) results in temporarily moving an intermediate valve body (332) away from a seating surface (354) to provide fast refilling of the control chamber (350) with fuel flowing through bores (360) connected to an inlet bore (358). A sharp closure of the valve member is achieved.
